

## Pizza3 - WORKSHOP - PostTreatment - Part 2

INRAE\Han Chen, Olivier Vitrac - rev. 2023-08-28, 2023-09-06

### Synopsis

The second part of the workshop will demonstrate how to interpret simulated data in space by projecting them on structured or unstructured grids, and to extract stresses.

The visualization techniques and use of the Verlet list are more sophisticated than in part 1. Computations are more expensive and require understanding of vectorial algebra.

The approaches are illustrated on more realistic data.

### Description and dependencies

```
%% Workshop Main File - Part 2
% This script demonstrates the data preprocessing, analysis, and visualization techniques
% using 'lamdumpread2', a custom function for reading LAMMPS dump files.

% File Structure (change your local path to reflect the content)
% |— example2.m (main developing file)
% |— notebook
% |   |— example2.mlx <-- this file
% |   ...
% |— data folder (dumps/pub1/)

%INRAE\Olivier Vitrac, Han Chen (rev. 2023-08-30,2023-08-31)

% Revision history
% 2023-09-04,05 implement grid interpolation
% 2023-09-06 deploy as a notebook
```

## 1. Initialization

### 1.1 General definitions

```
%% Initialization and Preprocessing
% -----
% Turn preprocessing on or off based on 'PREPROCESS_FLAG'.
% 'lamdumpread2' splits large 3D dump files if the flag is true.

statvec = @(f,before,after) dispf('%s: %s%d values | average = %0.5g %s', before, ...
    cell2mat(cellfun(@(x) sprintf('%0.1f%%> %10.4g | ', x, prctile(f, x)), {2.5, 25, 50, 75, 97.5}, 'UniformOutput', false)), ...
    length(f), mean(f),after); % user function to display statistics on vectors (usage: statvec(f,'myvar','ok'))

PREPROCESS_FLAG = false;
addpath(rootdir(pwd),'-begin')
if PREPROCESS_FLAG
    datafolder = '../dumps/pub1/';
    lamdumpread2(fullfile(datafolder,'dump.*'),'split'); % for large 3D
end

%% File-specific Processing (same file as in Example1.m but larger)
% -----
% A specific dump file is selected and pre-processed to extract data and
% save to default folders for further operations.
datafolder = '../dumps/pub1/';
dumpfile = 'dump.ulsphBulk_hertzBoundary_referenceParameterExponent+1_with1SuspendedParticle';
datafolder = lamdumpread2(fullfile(datafolder,dumpfile),'search'); % fix datafolder based on initial guess1.2
```

Look for 'dump.ulsphBulk\_hertzBoundary\_referenceParameterExponent+1\_with1SuspendedParticle'... (be patient)  
...found in '../dumps/pub1/numericalViscosimeter\_reference\_ulsphBulk\_hertzBoundary'

The dumpfile 'dump.ulsphBulk\_hertzBoundary\_referenceParameterExponent+1\_with1SuspendedParticle' has been found with the method 'splitfolder'  
in the folder: ../dumps/pub1/numericalViscosimeter\_reference\_ulsphBulk\_hertzBoundary  
the original search started in ../dumps/pub1  
The frame (split) folder is: ../dumps/pub1/numericalViscosimeter\_reference\_ulsphBulk\_hertzBoundary/PREFETCH\_dump.ulsphBulk\_hertzBoundary\_referenceParam  
The first frame (split) is located in: ../dumps/pub1/numericalViscosimeter\_reference\_ulsphBulk\_hertzBoundary/PREFETCH\_dump.ulsphBulk\_hertzBoundary\_refe  
The prefetch is split in several files.

1014 TIMESTEPS are available:

Column 01	Column 02	Column 03	Column 04	Column 05	Column 06	Column 07	Column 08	Column 09	Column 10
0	102000	204000	306000	408000	510000	612000	714000	816000	918000
1000	103000	205000	307000	409000	511000	613000	715000	817000	919000

## 2. Time-resolved interpretation: trajectories of selected particles

This section repeats the treatment performed in example1 (files are larger)

### 2.1 Select particles from one side of the channel

```

%% Data Preprocessing for Selected Particles
% -----
% This part is a repetition of the content of example1. It generate the streamlines for particles
% at the left. It requires 5 min and it can be skipped as it not used for stresses.
% note: the duration of the simulation enables the particles in the center (slowest part) to
% cross only half of the cell.

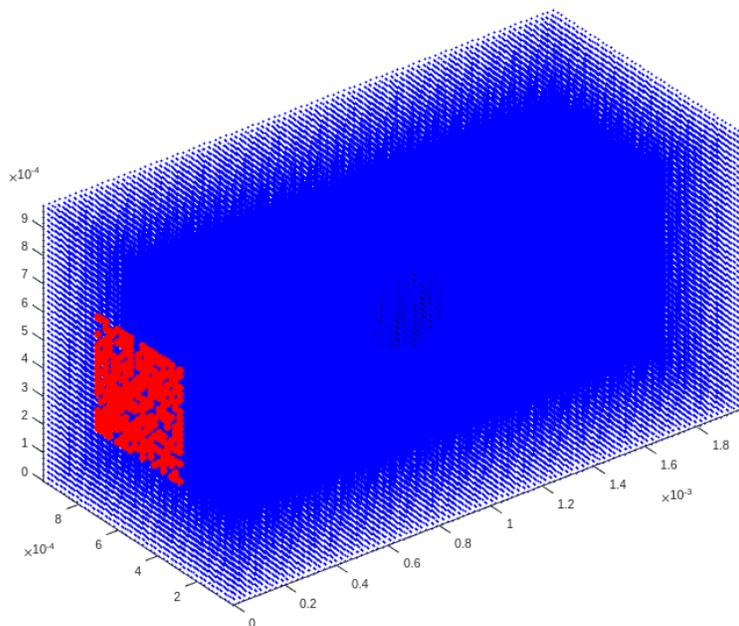

% Pick n particles randomly from the left inlet and included in the mask of the solid (initial frame)
n = 300;
tol = 0.5; % add 40% particles around
selectionbox = NaN(3,2);
selectionbox(iflow,:) = [X0.BOX(iflow,1), X0.BOX(iflow,1)+2*rbead];
selectionbox(iothers,:) = (1+tol)*(solidbox(iothers,2)-solidbox(iothers,1))*[-1 1]/2 ...
+ (solidbox(iothers,1)+solidbox(iothers,2)) * [1 1]/2;
ok = true(nfluidatoms,1);
for c = 1:3
    ok = ok & (fluidxyz(:,c)>=selectionbox(c,1)) & (fluidxyz(:,c)<=selectionbox(c,2));
end
icandidates = find(ok);

```

```

iselected = icandidates(MDunidrnd(length(icandidates),n));
selectedid = fluidid(iselected); % ID to be used
% plot selected particles and other ones
figure, hold on
plot3D(fluidxyz,'b.')
plot3D(fluidxyz(iselected,:), 'ro', 'markerfacecolor', 'r')
plot3D(solidxyz, 'ks', 'markerfacecolor', 'k')
view(3), axis equal

```

```

% Generate the trajectory for the selected particles (for all frames)
% All data are loaded with lamdumpread2() with a single call using 'usesplit'
% each split is loaded individually and only atoms matching selectedid are stored
% all atoms are sorted as selectedid (no need to sort them)
Xselection = lamdumpread2(fullfile(datafolder, dumpfile), 'usesplit', [], timesteps, selectedid);

```

hc = colorbar; hc.Label.String = 'velocity (m/s)';

```

## 3. Stress Analysis

This section is progressive and combine a broad variety of approaches with increasing refinements and sophistications

```
%% Stress Analysis in Reference Frame (PART 2)
% -----
% This part focuses on evaluating the mechanical interactions and stress in a particular
% frame. Specifically, we employ a late-stage frame (closer to steady-state conditions) to
% derive insights into the types of contacts between fluid and solid atoms.
%
% * `timestepforstress`: Time step selected for stress analysis.
% * `Xstress`: Data structure containing all relevant atomic information at the chosen time step.
% * `verletListCross`: A specialized Verlet list that segregates contacts based on atom types.
% * `isincontact`, `isincontactwithsolid`, `isincontactwithfluid`: Boolean fields that signify
% whether an atom is in contact, and with which type of atom.
%
% Here we rely heavily on a short-cut-off Verlet list for efficiency, separating cross-terms
% and characterizing specific types of atomic interactions.
clear Xsolid Xmiddle X0 Xselection streamline
```

### 3.1 Initialization and possibly loop on several frames

```
% General container for storing data for different timesteps
postdata = repmat(struct('type', 'Landshoff|Hertz', 'timestep', NaN, 'Xfluid', [], 'Xsolid', [], 'force', [], 0, 0));

% Extract the Specific Frame for Stress Interpretation
% Selects a time step that is presumably closer to the steady-state to perform stress analysis.
list_timestepforstress = unique(timesteps(ceil((0.1:0.1:0.9)*ntimesteps)));
nlist_timestepforstress = length(list_timestepforstress);
consideredtimesteps = 1:nlist_timestepforstress;

% === Loop on all selected time steps ===
altxt = {'no plot', 'plot'};

for i_timestepforstress = consideredtimesteps

    % current frame
    timestepforstress = list_timestepforstress(i_timestepforstress);
    Xstress = lamdumpread2(fullfile(datafolder, dumpfile), 'usesplit', [], timestepforstress); % middle frame
    doplot = ismember(timestepforstress, list_timestepforstress([1 end]));
    disp(['\n%s-\n[%d/%d] TIMESTEP = %d (%s)', repmat('-', 1, 40), i_timestepforstress, nlist_timestepforstress, timestepforstress, altxt{doplot+1}])

    % Categorization of Atom Types
    % Identifies the most and least populous atom types to discern between fluid and solid types.
    T = Xstress.ATOMS.type;
    natomspertype = arrayfun(@t) length(find(T==t)), atomtypes);
    [-, fluidtype] = max(natomspertype);
    [-, solidtype] = min(natomspertype);
    walltypes = setdiff(atomtypes, [fluidtype, solidtype]);

    % Boolean Classification of Atom Types
    Xstress.ATOMS.isfluid = Xstress.ATOMS.type==fluidtype;
    Xstress.ATOMS.issolid = Xstress.ATOMS.type==solidtype;

    % Verlet List Construction with Short Cutoff
    % Builds a Verlet list with a short cutoff distance, designed to identify only the closest neighbors.
    [verletList, cutoff, dmin, config, dist] = buildVerletList(Xstress.ATOMS, 3*rbead);

    % Partition Verlet List Based on Atom Types
    % This Verlet list is partitioned based on atom types, distinguishing between interactions
    % that are exclusively fluid-fluid, solid-fluid, or solid-solid.
    verletListCross = partitionVerletList(verletList, Xstress.ATOMS);

    % Identify Contacting Atoms
    % The atoms that are in contact with each other are identified.
    Xstress.ATOMS.isincontact = ~cellfun(@isempty, verletListCross);
    Xstress.ATOMS.contacttypes = cellfun(@(v) Xstress.ATOMS.type(v)', verletListCross, 'UniformOutput', false);

    % Identify Atoms in Contact with Solids and Fluids
    % Further filters the atoms in contact to identify which are in contact with solids and which with fluids.
    Xstress.ATOMS.isincontactwithsolid = cellfun(@(c) ismember(solidtype, c), Xstress.ATOMS.contacttypes);
    Xstress.ATOMS.isincontactwithfluid = cellfun(@(c) ismember(fluidtype, c), Xstress.ATOMS.contacttypes);

    % Flag Fluid Atoms in Contact with Solid and Vice Versa
    % Identifies fluid atoms that are in contact with solid atoms and solid atoms in contact with fluid atoms.
    Xstress.ATOMS.fluidincontactwithsolid = Xstress.ATOMS.isfluid & Xstress.ATOMS.isincontactwithsolid;
    Xstress.ATOMS.solidincontactwithfluid = Xstress.ATOMS.issolid & Xstress.ATOMS.isincontactwithfluid;

    % Identify Indices for Analysis
    % Indices of fluid and solid atoms that are in contact with each other.
    ifluidcontact = find(Xstress.ATOMS.fluidincontactwithsolid);
    isolidcontact = find(Xstress.ATOMS.solidincontactwithfluid);

 number of solid atoms in contact with fluid 580 (neighbors 1035)

### 3.2. Projection of velocity field on a regular grid

The interpolation process of large systems requires to be performed with `interp3SPHVerLet()` with the help of a Verletlist. The search for neighbors can be done for beads but also for arbitrary nodes from a mesh. The interpolation can be applied to scalar and vectorial fields. Once velocities are properly calculated, it is possible to derive streamlines.

With large grids, the calculations are very intensive and may require a lot of memory. Reduce the grid size if your experience memory errors.

```
%% === 3D view of the fluid velocity around the solid ===
DOINTENSIVECALC = true; % set it to false, to prevent intensive calculations
% Definition of the Viewbox (for all grid-based visualizations)
coords = {'x','y','z'}; % Cartesian coordinates
vcoords = cellfun(@(c) ['v',c],coords,'UniformOutput',false); % vx, vy, vz
% Extract the box around solid atoms and include fluid ones
fluidbox = [ min(Xstress.ATOMS{Xstress.ATOMS.isfluid,coords})
             max(Xstress.ATOMS{Xstress.ATOMS.isfluid,coords}) ]';
solidbox = [ min(Xstress.ATOMS{Xstress.ATOMS.issolid,coords})
             max(Xstress.ATOMS{Xstress.ATOMS.issolid,coords}) ]';

### 3.3 Landshoff forces

```

%% Landshoff forces in the fluid
%
% This section is dedicated to the calculation of Landshoff forces in the fluid medium.
% The computation is confined to a shell or "crown" around the solid particles.
% Here, we build a new Verlet list specific to the fluid particles around solid structures.
%
% * `Xfluidcontact_withneighbors`: Atomic information specifically for the fluid atoms in the vicinity of the solid.
% * `Vfluidcontact_withneighbors`: Verlet list constructed for these neighboring fluid atoms.
% * `FLandshoff`: Landshoff forces calculated based on the new Verlet list.
% * `f`: Magnitude of the Landshoff forces.
%
% Finally, visualization aids are employed to graphically represent these forces and their directions.

% Extract Information for Fluid Atoms in Contact with Neighbors
% Obtains the atomic information for fluid atoms in the vicinity of solid atoms, as identified earlier.
Xfluidcontact_withneighbors = Xstress.ATOMS(ifluidcontact_withneighbors,:);

% Verlet List Construction for Fluid Atoms

```

```

%%% Constructs a Verlet list for these neighboring fluid atoms with a larger cutoff (4*rbead).
Vfluidcontact_withneighbors = buildVerletList(Xfluidcontact_withneighbors,4*rbead);

## 4. Force Visualization

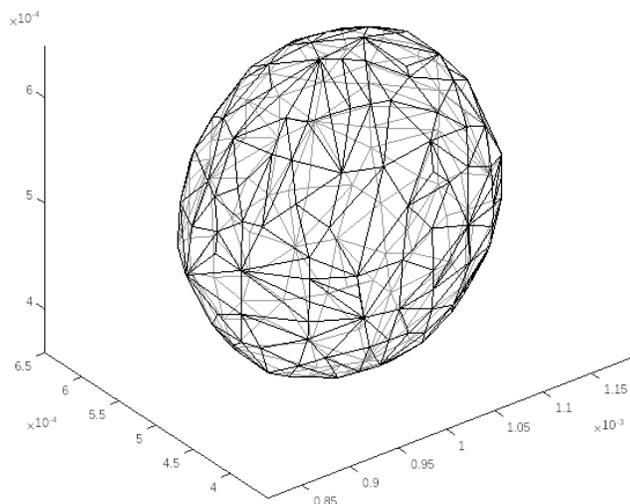

### 4.1 Solid visualization using a convex-hull

```

%% Visualization (bead-based) of Landshoff forces
% Creates a 3D visualization featuring both the solid structure and the fluid atoms under consideration.
% The Landshoff forces are represented as arrows originating from the fluid atoms.

% Tesselated Solid Visualization
% Utilizes Delaunay triangulation to represent the solid structure.
DT = delaunayTriangulation(double(Xstress.ATOMS{isolidcontact,{'x','y','z'}}));
K = convexHull(DT);
figure, hold on
trisurf(K, DT.Points(:,1), DT.Points(:,2), DT.Points(:,3), 'FaceColor', 'w','Edgecolor','k','FaceAlpha',0.6);
axis equal; view(3)

```

### 4.2. Basic visualization of Landshoff forces

```

%% Basic Visualization of Fluid Atoms and Landshoff Forces
% Landshoff forces are scaled and then visualized as arrows.
% fluid around
% scatter3D(Xfluidcontact_withneighbors{ind_withoutneighbors,{'x','y','z'}},f);
fmedian = median(flandshoff);
fmin = fmedian/50;
fscale = 4*rbead/fmedian;
start = Xfluidcontact_withneighbors{ind_withoutneighbors,{'x','y','z'}};
stop = start + Flandshoff * fscale;
start(flandshoff<fmin,:) = []; % non-significant forces are removed
stop(flandshoff<fmin,:) = [];
ha = arrow(start,stop,'length',4,'BaseAngle',60,'color','r');

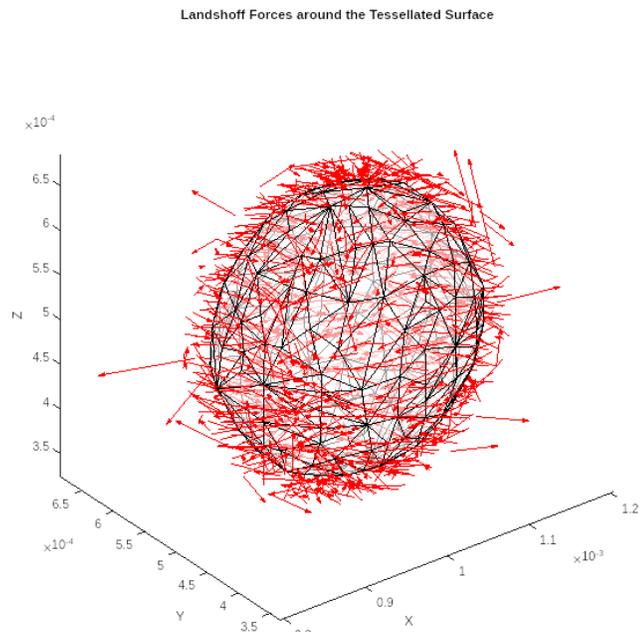

```

Warning: ARROW changed the axis limits on several axes when adding the arrows.  
Call ARROW FIXLIMITS to reset them now.

```

axis equal, view(3)
title('Landshoff Forces around the Tesselated Surface');
xlabel('X'); ylabel('Y'); zlabel('Z')

```

### 4.3. Advanced grid visualization of Landshoff forces

The following approach generalizes the quiver plot used for the velocity field

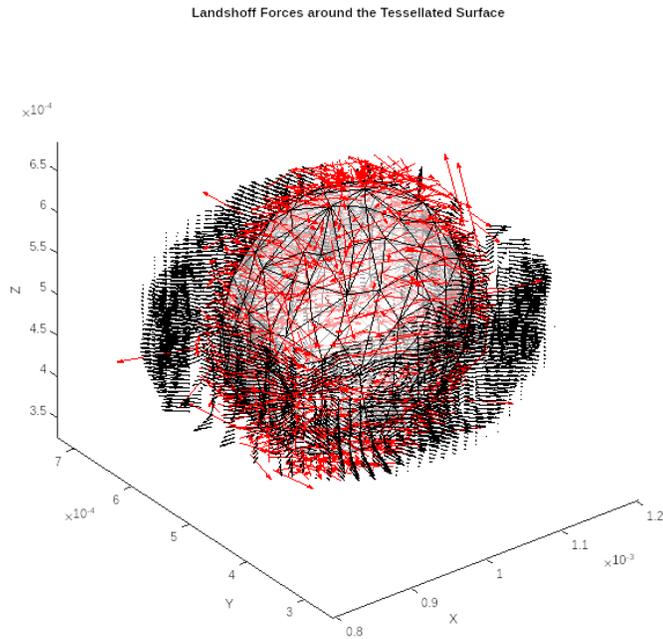

```
% Advanced LandShoff Visualization based on Grid Interpolation
coords = {'x','y','z'};
landshoffbox = [ min(Xfluidcontact_withneighbors(:,coords))
                max(Xfluidcontact_withneighbors(:,coords)) ]';
xlw = linspace(viewbox(1,1),viewbox(1,2),50);
ylw = linspace(viewbox(2,1),viewbox(2,2),50);
zlw = linspace(viewbox(3,1),viewbox(3,2),50);
[Xlw,Ylw,Zlw] = meshgrid(xlw,ylw,zlw);
XYZlgrid = [Xlw(:),Ylw(:),Zlw(:)];
XYZl = Xfluidcontact_withneighbors(:,coords); % kernel centers
% Interpolation at Grid Points of Flandshoff_all
VXYZl = buildVerletList({XYZlgrid XYZl},1.2*hLandshoff); % special grid syntax
```

```

## 5. Stress calculation and visualization

The difference between force and stress visualization is that you need to divide force by the surface area, where the force applies.

The current version use of example2 demonstrate the strategy without combining the method with the most advanced interpolation of forces on structured or unstructured mesh. For production, it is recommended to use forces which have be smoothed (interpolated) over a grid.

### 5.1 Template strategy

In the absence of grid, the results are not as smooth.

```

%% Project Landshoff Forces onto the Tessellated Surface
% Allocate space for the projected forces.
FprojectedN = zeros(size(Flandshoff));
FprojectedT = zeros(size(Flandshoff));
% Extract vertex coordinates from Delaunay Triangulation object.
vertices = DT.Points;
% Loop through all fluid atoms in contact with the solid.
for i = 1:length(ind_withoutneighbors)
    % Get the position of the current fluid atom.
    fluidPos = Xfluidcontact_withneighbors{ind_withoutneighbors(i),{'x','y','z'}};
    % Find the closest vertex on the tessellated surface.
    dists = sum((vertices - fluidPos).^2, 2);

```

```

[-, closestVertexIdx] = min(dists);
closestVertex = vertices(closestVertexIdx, :);
% Calculate the vector from the fluid atom to the closest surface vertex.
surfaceToFluidVec = fluidPos - closestVertex;
% Normalize the vector.
surfaceToFluidVec = surfaceToFluidVec / norm(surfaceToFluidVec);
% Get the Landshoff force acting on the fluid atom.
landshoffForce = Flandshoff(i, :);
% Project the Landshoff force onto the normal.
% Here, surfaceToFluidVec serves as the approximation of the outward normal at the closest vertex.
projectedForceN = dot(landshoffForce, surfaceToFluidVec) * surfaceToFluidVec;
% Store the projected force.
FprojectedN(i, :) = projectedForceN;
FprojectedT(i, :) = landshoffForce - projectedForceN;
end

% At this point, Fprojected contains the Landshoff forces projected onto the surface normal.
% Interpolation and Stress Magnitude Visualization
% Get faces and vertices from the tessellation.
faces = K; % Faces are given by the convex hull indices
vertices = DT.Points; % Vertex coordinates

% Loop over all faces to interpolate force and stress.
% Compute Barycentric Interpolation of Forces
% Initialize an array to store the interpolated forces and stresses
FNinterp_face = zeros(size(faces, 1), 3);
FTinterp_face = zeros(size(faces, 1), 3);
SNinterp_face = zeros(size(faces, 1), 3); % Normal stress per unit area
STinterp_face = zeros(size(faces, 1), 3); % Tangential stress per unit area

```

### 5.1.1 Stress at faces

```

% Loop over all faces.
for i = 1:size(faces, 1)
    % Vertices of the triangle.
    vertex_indices = faces(i, :);
    A = vertices(vertex_indices(1), :);
    B = vertices(vertex_indices(2), :);
    C = vertices(vertex_indices(3), :);
    % Surface area of the triangle using Heron's formula.
    AB = norm(A - B);
    AC = norm(A - C);
    BC = norm(B - C);
    s = (AB + AC + BC) / 2;
    area_triangle = sqrt(s * (s - AB) * (s - AC) * (s - BC));
    % Normal to faces
    N = cross(B - A, C - A);
    N = N / norm(N); % Normalizing the normal vector
    % Forces at the vertices.
    F_A = FprojectedN(vertex_indices(1), :) + FprojectedT(vertex_indices(1), :);
    F_B = FprojectedN(vertex_indices(2), :) + FprojectedT(vertex_indices(2), :);
    F_C = FprojectedN(vertex_indices(3), :) + FprojectedT(vertex_indices(3), :);
    % The centroid (P) of the triangle for interpolation.
    P = (A + B + C) / 3;
    % Barycentric weights.
    ABC_inv = inv([A; B; C]);
    w = ABC_inv * P';
    % Interpolate the force at the centroid.
    Finterp = w(1) * F_A + w(2) * F_B + w(3) * F_C;
    % Decompose the force into normal and tangential components
    F_N = dot(Finterp, N) * N; % only the normal force is trivial to compute
    F_T = Finterp - F_N; % by subtraction we get the tangential
    % Store interpolated force.
    Finterp_face(i, :) = Finterp;
    % Compute normal and tangential stress per unit area (Force/Area)
    SNinterp_face(i, :) = F_N / area_triangle;
    STinterp_face(i, :) = F_T / area_triangle;
end
% Compute the magnitude of interpolated stress.
face_force_magnitude = sqrt(sum(Finterp_face.^2, 2));
face_stressN_magnitude = sqrt(sum(SNinterp_face.^2, 2));
face_stressT_magnitude = sqrt(sum(STinterp_face.^2, 2));

```

### 5.1.2. Stress at vertices

```

% Add the smoothed force at vertices
% In computational geometry, the "valence" of a vertex refers to the number of edges
% (or equivalently, faces for a triangular mesh) incident to it. Valence can serve as
% an important metric in mesh quality and adaptivity considerations.
% In our case, the valence is expected high (up to 11,12 faces per vertex), then poor mesh
uniq_vertex_indices = unique(faces(:)); % Find unique vertices used in faces
uniq_vertices = vertices(uniq_vertex_indices, :); % Create a new vertices array based on these unique indices
mapping = NaN(size(vertices, 1), 1); % Create a mapping from old vertex indices to new ones
mapping(uniq_vertex_indices) = 1:length(uniq_vertex_indices);
uniq_faces = mapping(faces); % Update the faces array to reflect new vertex indices
% Initialize interpolated forces at vertices
Finterp_vertex = zeros(size(uniq_vertices, 1), 3);
SNinterp_vertex = zeros(size(uniq_vertices, 1), 3);
STinterp_vertex = zeros(size(uniq_vertices, 1), 3);
% Create a mapping from vertices to faces
vertex_to_faces = cell(size(uniq_vertices, 1), 1);

```

```

for i = 1:size(uniq_faces, 1)
    for j = 1:3 % for each Vertex
        vertex_to_faces{uniq_faces(i, j)} = [vertex_to_faces{uniq_faces(i, j)}; i]; % we add the ith face
    end
end
% Interpolate forces at each vertex
for i = 1:size(uniq_vertices, 1)
    adjacent_faces = vertex_to_faces{i};
    if ~isempty(adjacent_faces)
        Finterp_vertex(i, :) = mean(Finterp_face(adjacent_faces, :), 1);
        SNinterp_vertex(i, :) = mean(SNinterp_face(adjacent_faces, :), 1);
        STinterp_vertex(i, :) = mean(STinterp_face(adjacent_faces, :), 1);
    end
end
end
vertex_force_magnitude = sqrt(sum(Finterp_vertex.^2, 2));
vertex_stressN_magnitude = sqrt(sum(SNinterp_vertex.^2, 2));
vertex_stressT_magnitude = sqrt(sum(STinterp_vertex.^2, 2));

```

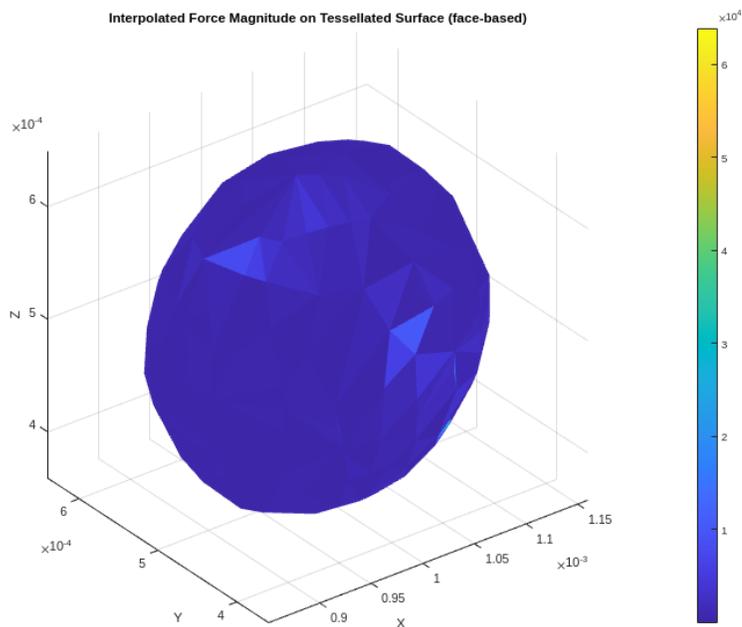

## 5.2. Visualization

### 5.2.1. Face-based visualization

```

% Visualization (face-based, less smooth)
